Multiple Linear Regression extends bivariate linear regression by incorporating multiple independent variables (predictors). The simple linear model with 1 predictor is expressed as $Y = \beta_0 + \beta_1X + \epsilon$. When adding a second predictor, the model is expressed as $Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \epsilon$. When adding more than 2 predictors, the model is expressed as $Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \ldots + \epsilon$. In model building, a residual is what is left after the model is fit. It is the difference between the observed values and the values predicted by the model.

Assumptions.

The assumptions for the Multiple Linear Regression are the same as for the Simple Linear Regression model (see slides 15-17).

Multiple regression in behavioral research, third edition. New York: Harcourt. Brace College Publishers. Los Angeles: SAGE, 2017. 817 p. Linear models, their variants, and extensions—the most important of which are generalized linear models—are among the most useful and widely used statistical tools for social general research. This book aims to provide an accessible, in-depth, modern treatment of regression analysis, linear models, generalized linear models, and closely related methods. The book should be of interest to students and researchers in the social sciences. Although the specific choice of methods and examples reflects this readership.
As a result, BIC has become quite popular for model selection in sociology, particularly in log-linear and other models for categorical data. Two other difficulties with the use of $\chi$-values for model selection are also prevalent in sociology, although they are less obvious. They arise when many statistical models are implicitly considered in the earlier stages of a data analysis. In Section 4 I derive the BIC approximation and equivalent expressions useful for specific models used in social research. I discuss the interpretation of BIC and why it sometimes leads to different conclusions than $P$-values. In particular, BIC tends to favor simpler models and null hypotheses more than do $P$-values in large data sets.
